

Chapter 3

Basic Data Types

Outline

- Data types
- Operators and expressions

Data Types

Variable and Constant

Variable → `num` = `12400` ← Constant

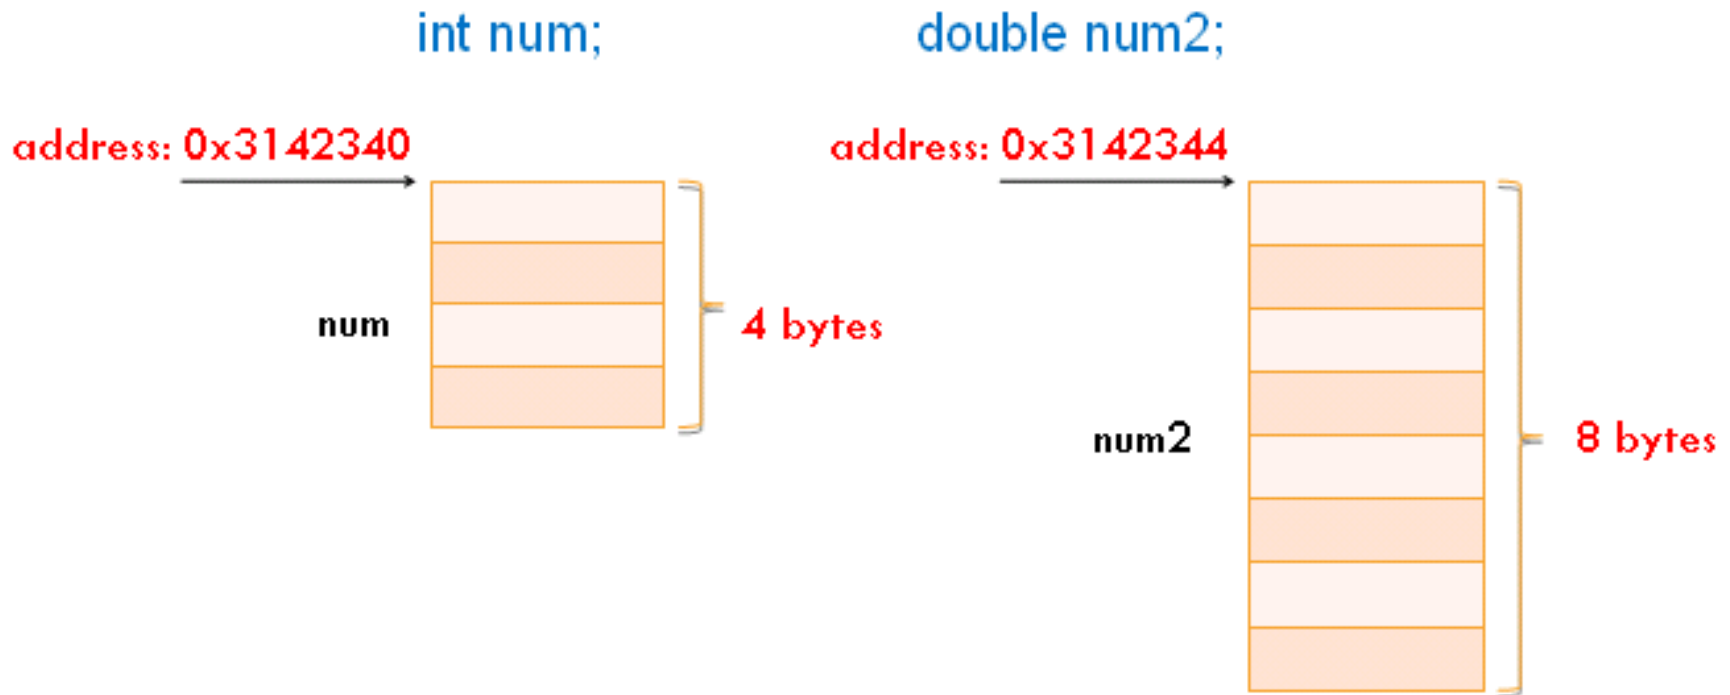

- Variable
 - Correspond to locations of the computer's memory
 - Has a name and type, which are fixed after declaration
 - Has a value, which can be updated

- Constant
 - Does not change during the execution of the program

Memory Concepts

- Declare a variable
 - Allocate memory to a variable

Memory Concepts (Cont.)

- Assign a value to a variable

`int num;`

address: **0x3142340**

num

4 bytes

`num = 2;`

address: **0x3142340**

num

4 bytes

`num = 55;`

address: **0x3142340**

num

4 bytes

Data Types

Data Type	Description	# of bytes	Range
int	integer	4	-2147483648 ~ 2147483647
long int	long integer	4	-2147483648 ~ 2147483647
short int	short in	2	-32768 ~ 32767
char	character	1	0 ~ 255
float	floating point	4	1.2e-38 ~ 3.4e38
double	double floating point	8	2.2e-308 ~ 1.8e308

Note: The size of each data type may vary from different compilers

Overflow

- Definition:

- The **value** assigned to a variable is **larger than** or **smaller than** the range of the corresponding data type.

- Overflow example:

- `short int num = 40000; /* short: -32768~32767 */`
- `unsigned short int num = 700000; /* unsigned short: 0~65535 */`
- `short int num_a, num_b, sum;`
`num_a = 30000;`
`num_b = 30000;`
`sum = num_a + num_b; /* num_a + num_b = 60000 */`

Overflow: Example

```

01 #include <stdio.h>
02 #include <stdlib.h>
03 int main(void)
04 {
05     short int sum, num;           /* declare "num" and "sum" */
06     num = 0x7FFF;                /* set "num" to 32767 */
07     sum = num + 1;
08     printf("num + 1 = %d\n", sum); /* print variable */
09
10     sum = num + 2;
11     printf("num + 2 = %d\n", sum); /* print variable */
12     system("pause")
13     return 0;
14 }

```

Long
integer

0x7FFF=32767

Output:

```

num + 1 = -32768
num + 2 = -32767

```

Overflow: 2's Complement

One's complement: if sign bit = 1, invert from 0 to 1 and from 1 to 0

Two's complement: One's complement + 1

The value of an integer variable: $(-1)^{\text{sign-bit}} * (\text{two's complement})_2$

sign bit Max positive value = $(-1)^0 * (111111..11)_2 = 32767$

0	1	1	1	1	...	1	1	1	1
---	---	---	---	---	-----	---	---	---	---

sign bit Min negative value = $(-1)^1 * (10000...00)_2 = -32768$

1	0	0	0	0	...	0	0	0	0
---	---	---	---	---	-----	---	---	---	---

- If sign bit = 1, the variable is negative
- If sign bit = 0, the variable is non-negative

Two's complement (8 bits)

00000000	00000000 = 0
00000001	00000001 = 1
....	
01111111	01111111=127
11111111	-(00000001) = -1
....	
10000000	-(10000000) = -128

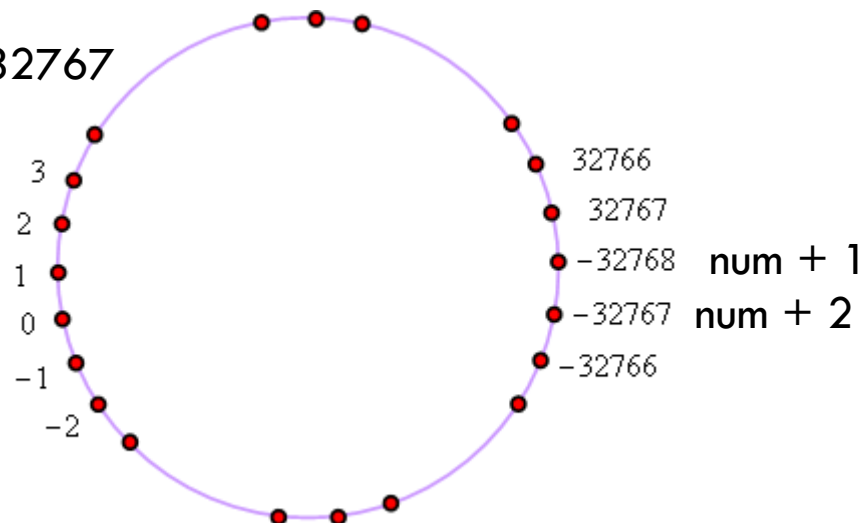

Overflow: Signed Variable

sign bit Max positive value = $(-1)^0 * (111111..11)_2$

0	1	1	1	1	...	1	1	1	1	
									+	1
1	0	0	0	0	...	0	0	0	0	

short int num = 32767

Unsigned Variables

- Let the variable always have a positive value

Data Type	Description	# of bytes	Range
unsigned int	Unsigned integer	4	0 ~ 4294967295
unsigned long int	Unsigned long integer	4	0 ~ 4294967295
unsigned short int	Unsigned short in	2	0 ~ 65535

- Why should we use unsigned variables?
 - Increase the range of a variable if we are very sure that the variable must not be a negative value.
 - Example: The number of students in a class
 - Save the size of a variable (in terms of memory)
 - Example: For a variable ranging from 0 to 40000, we can declare it as **int** (4 bytes) or **unsigned short int** (2 bytes)

Data Type: char

- Character, which occupies one byte
 - `char ch = '1'; /* the character '1' != integer 1 */`
`ch = 'A';`
`ch = 'a'; /* 'A' != 'a' */`
`ch = 97; /* Assign the character whose ASCII is 10 ('a') to ch. */`
- There are totally **256** characters
 - Not all characters are printable
 - Check the table mapping each character to its ASCII code (<http://en.wikipedia.org/wiki/ASCII>)

Print a Character

```
01 #include <stdio.h>
02 #include <stdlib.h>
03 int main(void)
04 {
05     char ch = 'a' , ch2 = 100;          /* declare a character */
06     printf("ch = %c\n", ch); /* print the character 'a' */
07     printf("ASCII of ch = %d\n", ch); /* print the ASCII of 'a' */
08
09     printf("ASCII 100 = %c\n", ch2); /* print the variable
10                                     whose ASCII is 100 */
12     system("pause");
13     return 0;
14 } /* end of main() */
```

ch = a
ASCII of ch = 97
ASCII 100 = d

Escapes

Escape sequence	Description	ASCII
\a	Alert	7
\b	Backspace	8
\n	New line	10
\r	Carriage return	13
\0	Null character	0
\t	Tab	9
\\	Backslash (\)	92
\'	Single quote (')	39
\"	Double quote (")	34

Data type: float

- Declare a float variable

- float f1 = 123.45**F**;

float

- float f1 = 1.2345E2;

- float f1 = 0.00123;

- float f1 = 1.23E-3**F**;

float

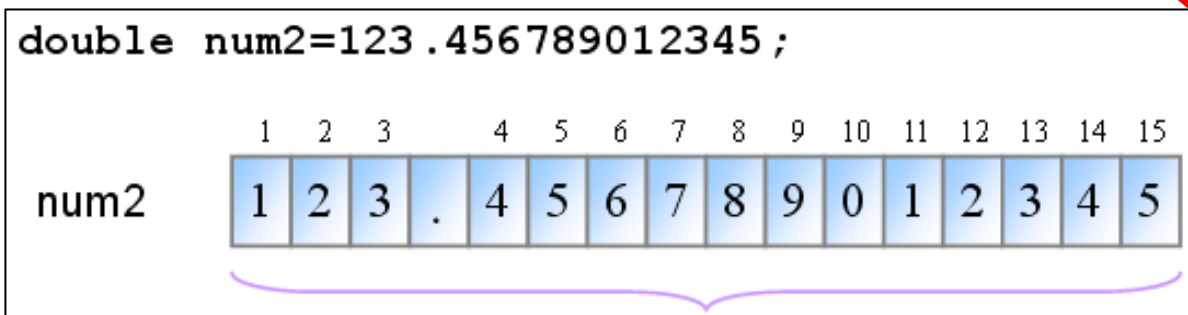

- Print a floating variable

- **printf("f1 = %f\n", f1);**

Data type: double

- 2.2E-308 ~ 1.8E308
- Precision of float: 7~8 bits
- Precision of double: 15~16 bits

Must be abandoned due to the limited memory size

Library Function *sizeof()*

- Calculate the size of data types
 - `sizeof(int); // 4 bytes`
 - `sizeof(double); // 8 bytes`
- Calculate the size of a variable
 - `int num;`
`sizeof(num); // 4 bytes`
 - `sizeof(2L); // 4 bytes`
- Unit: ***byte***

Type Conversion

- Convert a variable to another type:

(new type) variable

```
01 int num = 12;  
02 float total;  
03 total = (float) num;
```

Type Conversion

• Example 1

float

```
01 float f1 = 3.1, f2 = 3.2F;  
02 printf ("f1 = %f, f2 = %f\n", f1, f2);  
03 printf ("f1 = %d, f2 = %d\n", (int)f1, (int)f2);
```

Output:

```
f1 = 3.1, f2 = 3.2  
f1 = 3, f2 = 3
```

```
01 int num = 5;  
02 printf ("num/2 = %d\n", num/2);  
03 printf ("float: num/2= %f\n", (float)num/2);
```

Output:

```
num/2 = 2  
float: num/2 = 2.500
```

Operators and Expressions

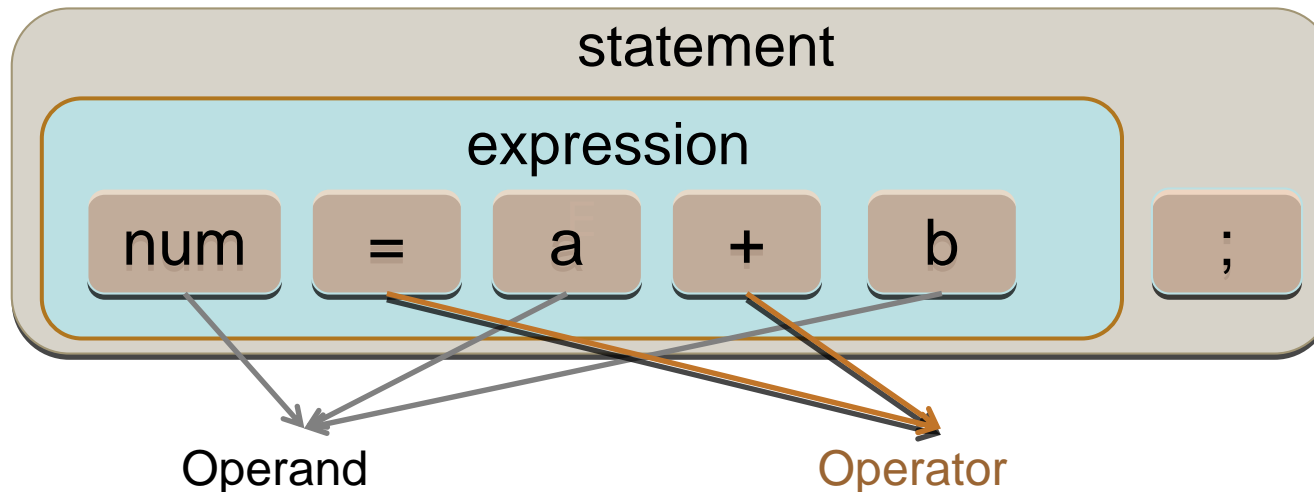

Expression

- Expression is composed of operands and operators
 - **Operand:** *variables* or *constant*, such as num, 10, etc.
 - **Operator:** +, -, *, /, %, =, >, <, &, |, !, (,)
 - Example:

num = a + b;

age = age + 1;

Arithmetic Operator

Operation	Arithmetic operator	Algebraic expression	C expression
Addition	+	$a + b$	$a + b$
Subtraction	-	$a - b$	$a - b$
Multiplication	*	ab	$a * b$
Division	/	a / b	a / b
Remainder	%	$a \text{ mod } b$	$a \% b$

- Division
 - $(\text{int}) / (\text{int}) = (\text{int})$ (example: $5 / 2 = 2$)
 - $(\text{float}) / (\text{int}) = (\text{float})$ (example: $5.0 / 2 = 2.5$)
 - $(\text{int}) / (\text{float}) = (\text{float})$ (example: $5 / 2.0 = 2.5$)
- Remainder
 - $10 \% 3 = 1$
 - Print %: use `%%` (example: `print("10%%3 = %d\n", 10 % 3);`)

Operator Precedence

- Some arithmetic operators act before others.
 - Multiplication and division before addition and subtraction.
 - Use **parenthesis** to specify precedence.
 - Example: computer the average of a, b, and c
 - **Do not use:** $a + b + c / 3$
 - **Use:** $(a + b + c) / 3$

Operator	Precedence
()	Evaluated first; Inner to outer; Left to right
*, /, %	Evaluated second; Left to right
+, -	Evaluated last; Left to right

Operator Precedence: Example

1. $y = \underline{2 * 5} * 5 + 3 * 5 + 7;$

2. $y = \underline{10 * 5} + 3 * 5 + 7;$

3. $y = 50 + \underline{3 * 5} + 7;$

4. $y = \underline{50 + 15} + 7;$

5. $y = 65 + 7;$

6. $y = 72;$

Equality and Relationship Operator

Operator	Condition	Meaning
Equality operator		
==	$x == y$	x is equal to y
!=	$x != y$	x is not equal to y
Relationship operator		
>	$x > y$	x is larger than y
<	$x < y$	x is smaller than y
>=	$x >= y$	x is larger than or equal to y
<=	$x <= y$	x is smaller than or equal to y

- Return **“truth” (1)** if the condition is true; otherwise, **“false” (0)**.
- Note that **==** (equality operator) is different from **=** (assignment operator)

Logical Operator

Operator	Condition	Meaning
&&	$x \ \&\& \ y$	x and y
	$x \ \ y$	x or y

Truth Table

&&	T	F
T	T	F
F	F	F

	T	F
T	T	T
F	T	F

F: 0

T: any non-zero value

$10 \ \&\& \ 0 \ \rightarrow \ \text{False}$

$5 \ || \ 0 \ \rightarrow \ \text{Truth}$

Used in flow control; can not be put in the statement (ex: $a = b \ \&\& \ c$)

Concatenation Operator

Operator	Condition	Meaning
&	$x \& y$	x and y (bit-wise and)
	$x y$	x or y (bit-wise or)
~	$\sim x$	not x (bit-wise inverse)

$12 \& 4 = 4$ $(00001100)_2 \& (00000100)_2 = (00000100)_2$
 $12 \& 2 = 0$ $(00001100)_2 \& (00000010)_2 = (00000000)_2$
 $12 | 2 = 14$ $(00001100)_2 | (00000010)_2 = (00001110)_2$
 $\sim 12 = -13$ $\sim(00001100)_2 (11110011)_2$

```
printf("%d %d %d %d", 12&4, 12&2, 12 | 2, ~12);
```

4 0 14 -13

Output:

Unary Operator

- Need only one operand

– +5 /* positive 5 */

– -a /* = -1 * a */

– !a /* not operator; if a = 0, !a = 1; otherwise, if a \neq 0, !a = 0 */

```
01 int a = +5;
02 int b = -5;
03 int c = !a;
04 a = 0;
05 int d = !a;
06 int e = !b;
07 printf("c = %d, d = %d, e = %d\n", c, d, e);
```

Output:

c = 0, d = 1, e = 0

++ and --

Operator	Condition	Meaning
++	x++	$x = x + 1$
	++x	$x = x + 1$
--	x--	$x = x - 1$
	--x	$x = x - 1$

- **x++**: execute the statement first, and then add x by 1
 - `int x = 5;`
`int y = (x++) + x + 5;` (result: $y = 5 + 5 + 5 = 15$; $x = 6$)
- **++x**: add x by 1, and then execute the statement
 - `int x = 5;`
`int y = (++x) + x + 5;` (result: $y = 6 + 5 + 5 = 17$; $x = 6$)

Compound Operator

Operator	Condition	Meaning
<code>+=</code>	<code>x += 5</code>	<code>x = x + 5</code>
<code>-=</code>	<code>x -= 5</code>	<code>x = x - 5</code>
<code>*=</code>	<code>x *= 5</code>	<code>x = x * 5</code>
<code>/=</code>	<code>x /= 5</code>	<code>x = x / 5</code>
<code>%=</code>	<code>x %= 5</code>	<code>x = x % 5</code>
<code>&=</code>	<code>x &= 5</code>	<code>x = x & 5</code>
<code> =</code>	<code>x = 5</code>	<code>x = x 5</code>

No space before “=”

Operator Precedence

Precedence	Operators	Associative
1	++, --	Right to left
2	(), []	Left to right
3	!, -(negative), ~	Right to left
4	*, /, %	Left to right
5	+, -	Left to right
6	<<, >>	Left to right
7	>, >=, <, <=	Left to right
8	==, !=	Left to right
9	&	Left to right
10	^	Left to right
11		Left to right
12	&&	Left to right
13		Left to right
14	?:	Right to left
15	=	Right to left

Example

```
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    int a = 2;
    int b = 5;
    int c = 10;
    int e;
    e = ++a + ++c/b+(c-2*b)|a&5 ;
    printf("a = %d, e = %d", a,e);
    system("pause");
}
```

Output:

a = 3, e=7

Lab 03

- Write a program to print the ASCII codes of 'a', '&' and '\n'.
- Use ***sizeof()*** to show the size of the data types "char", "short", "int", "float", and "double".
